ECE 356 Winter 2018 1/1

For the following transaction schedule, fill in the RW-timestamps for data items a and b, assuming we use the simple timestamp-ordering protocol.

How would the answer change if we used the Thomas Write Rule?

| <i>T</i> ₁ | T_2 | <i>T</i> ₃ | $TS_r(a)$ | $TS_w(a)$ | $TS_r(b)$ | $TS_w(b)$ |
|-----------------------|-------|-----------------------|-----------|-----------|-----------|-----------|
| ra | | | | | | |
| | r_b | | | | | |
| | | r _a | | | | |
| Wa | | | | | | |
| | ra | | | | | |
| | | W_b | | | | |
| r_b | | | | | | |
| | W_b | | | | | |
| | | W_a | | | | |

ECE 356 Winter 2018 2

Exercise 9-1 Solution

| <i>T</i> ₁ | <i>T</i> ₂ | <i>T</i> ₃ | $TS_r(a)$ | $TS_w(a)$ | $TS_r(b)$ | $TS_w(b)$ |
|-----------------------|-----------------------|-----------------------|-----------|----------------------------------|-----------|------------------------------------|
| ra | | | 1 | | | |
| | r_b | | | | 2 | |
| | | r _a | 3 | | | |
| Wa | | | | 1<3, abort <i>T</i> ₁ | | |
| | r _a | | 3 | | | 2 |
| | | W_b | | | | 3 |
| r_b | 147. | | | | | 2<3, abort <i>T</i> ₂ |
| | W_b | 147 | | 3 | | 2 \3 , aboit 1 ₂ |
| | | W_a | | 3 | | |

If we used the Thomas Write Rule, T_2 would not need to abort just because it wanted to write a value that would have already been overwritten by T_3 , and the write would have been ignored instead.

ECE 356 Winter 2018 3/1

Exercise 9-2

Under what conditions does the phantom read phenomenon occur?

ECE 356 Winter 2018 4/1

Phantom reads happen when reads and writes conflict on unisolated, non-tuple data.

e.g.

Query 1: SELECT a COUNT of the number of Math professors at Waterloo.

Query 2: INSERT a Waterloo Math professor.

Transaction 1: Run Query 1 twice.

Transaction 2: Run Query 2 once.

This poses a problem for serialized isolation. The result of the SELECT will differ based on whether it runs before or after the INSERT. If the SELECTs happen on either side of the INSERT, then Transaction 1 will see inconsistent information. In serialized isolation, each transaction should be able to assume that it is the only transaction running at a time.

This is allowed to happen since we can't lock rows that do not exist (yet). We fix this with a protocol that locks index leaf nodes, under the assumption that every guery uses an index.

ECE 356 Winter 2018 5/1

Suppose we need to recover from a system failure, and have the transaction log below.

Assuming we use an immediate update protocol with checkpointing, what log entries does the recovery system need to add to restore the database to a consistent state?

| action | transaction | item | val | vaľ | flags |
|------------------|---------------------------|------|-----|-----|-----------|
| start | <i>T</i> ₁ | | | | |
| write | T_1 | а | 1 | 2 | |
| write | T_1 | a | 2 | 3 | |
| checkpoint | [<i>T</i> ₁] | | | | |
| want to abort | T_1 | | | | |
| write | T_1 | a | - | 2 | redo-only |
| start | T_2 | | | | |
| write | T_2 | b | 5 | 6 | |
| write | T_2 | b | 6 | 7 | |
| (system failure) | | | | | |

ECE 356 Winter 2018 6/1

Exercise 9-3 Solution

| action | transaction | item | val | val | flags |
|------------------|---------------------------|------|-----|-----|-----------|
| start | <i>T</i> ₁ | | | | |
| write | T_1 | а | 1 | 2 | |
| write | T_1 | a | 2 | 3 | |
| checkpoint | [<i>T</i> ₁] | | | | |
| want to abort | T_1 | | | | |
| write | T_1 | а | - | 2 | redo-only |
| start | T_2 | | | | |
| write | T_2 | b | 5 | 6 | |
| write | T_2 | b | 6 | 7 | |
| (system failure) | | | | | |
| write | <i>T</i> ₂ | b | - | 6 | redo-only |
| write | T_2 | b | - | 5 | redo-only |
| abort | T_2 | | | | |
| write | T_1 | a | - | 1 | redo-only |
| abort | T_1 | | | | |

ECE 356 Winter 2018 7/1

Where do the following recovery protocols belong in the table below?

- deferred update
- **2** immediate update (*can* persist prior to commit)
- 3 strict immediate update (persist changes immediately)

| | redo | no-redo |
|---------|------|---------|
| undo | | |
| no-undo | | |

ECE 356 Winter 2018 8/1

Exercise 9-4 Solution

| | redo | no-redo | |
|---------|------------------|----------------------------|--|
| undo | immediate update | strict immediate update | |
| no-undo | deferred update | (this is called giving up) | |

ECE 356 Winter 2018 9/1

Exercise 9-5

What data is logged in order for the ARIES protocol to restore from a checkpoint?

ECE 356 Winter 2018 10 / 1

Exercise 9-5 Solution

In an ARIES checkpoint, the transaction table (TT) and dirty page table (DPT) at the time of checkpoint are written to the log.

The TT needs to know the IDs of the active transactions, the last LSN associated with each transaction, and the status of each transaction.

The DPT needs to know the IDs of the dirty pages (those that require updates), and the most recent (greatest) LSN associated with each page.

Recall that LSNs are written only for:

- write an update
- 2 commit transaction
- 3 abort transaction
- 4 undo an update
- 5 end transaction

ECE 356 Winter 2018 11/

Suppose a checkpoint is made between LSN 7 and 8 in the following schedule.

What data is stored in the transaction table and the dirty page table?

Where should the REDO phase start scanning for operations?

| Lsn | Last_lsn | Tran_id | Туре | Page_id | Other_information |
|-----|------------------|----------------|--------|---------|-------------------|
| 1 | 0 | T_1 | update | С | |
| 2 | 0 | T_2 | update | В | |
| 3 | 1 | T ₁ | commit | | |
| 4 | begin checkpoint | | | | |
| 5 | end checkpoint | | | | |
| 6 | 0 | T ₃ | update | Α | |
| 7 | 2 | T_2 | update | С | |
| 8 | 7 | T_2 | commit | | |

ECE 356 Winter 2018 12/

Exercise 9-7

Why is it important for the ARIES protocol to look for the most recent end-checkpoint log record as opposed to the most recent start-checkpoint log record during its analysis phase (finding TT and DPT at last checkpoint)?

ECE 356 Winter 2018 13 / 1

Exercise 9-7 Solution

The end-checkpoint log entry tells us that the TT and DPT have been fully written and that the checkpoint completed successfully. The log entry also contains the LSN of the corresponding start-checkpoint log entry, which marks where to start reading the TT and DPT.
